OROFACIAL PAIN
OCTOBER 2013 – OCTOBER 2014

Orofacial Pain

The general dentist and dental specialist treat patients with pain on a daily basis. Orofacial pain is pain perceived in the face and/or oral cavity. It is caused by diseases or disorders of regional structures, by dysfunction of the nervous system, or through referral from distant sources.

Treatment of orofacial pain is a specialty in dentistry in many parts of the world and an emerging area of specialization in others.

In addition to the diagnosis and treatment of acute dental pain and pathology, such as that which may arise from trauma, infection, or other odontogenic origin, the orofacial pain dentist has the responsibility to diagnose and treat nonodontogenic orofacial pain—pain that is often chronic and persistent, multifactorial and complex, distressing, and debilitating. Inadequate knowledge of the etiopathology of pain and the neurobiological mechanisms underlying persistent pain can lead to inaccurate diagnoses and subsequent ineffective or harmful treatment. It is also the responsibility of the orofacial pain dentist to assess the need for multidisciplinary pain management and to make appropriate referrals in a timely manner.

The complexity of the spectrum of orofacial pain disorders is compounded by the close proximity of numerous anatomical structures, including the eyes, nose, teeth, tongue, sinuses,

ears, regional muscles, and the temporomandibular joints. These structures may be the source of facial pain that can refer to nearby but uninvolved areas. For example, it is not uncommon for cross-referral to occur between headaches and other orofacial pain conditions.ⁱ

Numerous paradigms exist to evaluate and treat orofacial pain successfully. One such organized diagnostic approach categorizes orofacial pain into four groups based on the underlying pain mechanisms—namely, musculoskeletal, neuropathic, neurovascular, and psychogenic pain. The accompanying Global Year Against Orofacial Pain Fact Sheets address these four themes.
